

# Haskell4Life:

## Types and Typeclasses

Sergiu Ivanov

`sergiu.ivanov@lacl.fr`

Slides and code examples available online:

`http://lacl.fr/~sivanov/doku.php?id=en:  
haskell\_for\_life`

What is a class?

What is a type?

# Outline

1. Vague Definitions
2. Algebraic Data Types
3. Parameterised and Recursive Data Types
4. Typeclasses

# Outline

3. Parameterised and Recursive Data Types
4. Typeclasses

# Classes and Types

A **class/type** is a **set** of objects sharing a **property**.

# Classes and Types

A **class/type** is a **set** of objects sharing a **property**.

# Classes and Types

A **class/type** is a **set** of objects sharing a **property**.

Inheritance = set inclusion

# Classes and Types

A **class/type** is a **set** of objects sharing a **property**.

Inheritance = set inclusion

house  $\subseteq$  building

# Classes and Types

A **class/type** is a **set** of objects sharing a **property**.

Inheritance = set inclusion

house  $\subseteq$  building

Every **house** is a **building**, but **not** every **building** is a **house**.

# Typeclasses in Haskell: Vague Idea

A **typeclass** is a **collection** (class) of **types**.

## Typeclasses in Haskell: Vague Idea

A **typeclass** is a **collection** (class) of **types**.

**Typeclasses** in Haskell  $\neq$  **classes** in other languages.

## Typeclasses in Haskell: Vague Idea

A **typeclass** is a **collection** (class) of **types**.

**Typeclasses** in Haskell  $\neq$  **classes** in other languages.

**Classes** in other languages  $\sim$  **types** in Haskell

The use of the word class to refer to different things is just a “coincidence”.

# Outline

1. Vague Definitions
2. Algebraic Data Types
3. Parameterised and Recursive Data Types
4. Typeclasses

## Defining a New Datatype

```
data BookInfo = Book Int String [String]
               deriving ( Show )
```

## Defining a New Datatype

```
data type name BookInfo = Book Int String [String]
      deriving ( Show )
```

## Defining a New Datatype

data `BookInfo` = `Book` `Int` `String` `[String]`  
`deriving ( Show )`

Annotations in the diagram:  
- `BookInfo` is labeled "type name".  
- `Book` is labeled "data constructor".

## Defining a New Datatype

data `BookInfo` = `Book` `Int` `String` [`String`]  
`deriving` ( `Show` )

Annotations in the diagram:

- `BookInfo`: type name
- `Book`: data constructor
- `Int`: first field

## Defining a New Datatype

```
data BookInfo = Book Int String [String] deriving (Show)
```

Diagram illustrating the components of the `data` declaration:

- `BookInfo`: type name
- `Book`: data constructor
- `Int`: first field
- `String`: second field
- `[String]`: third field
- `deriving (Show)`: deriving clause

## Defining a New Datatype

```
data BookInfo = Book Int String [String]
  deriving (Show)
```

Annotations:

- type name: `BookInfo`
- data constructor: `Book`
- first field: `Int`
- second field: `String`
- third field: `[String]`
- automatically derive show: `Show`

## Defining a New Datatype

```
data BookInfo = Book Int String [String]
  deriving ( Show )
```

Annotations in the diagram:

- type name**: points to `BookInfo`
- data constructor**: points to `Book`
- first field**: points to `Int`
- second field**: points to `String`
- third field**: points to `[String]`
- automatically derive show**: points to `Show`

show converts “anything” to String.

## Constructing and Deconstructing a Value

```
λ> let hp = Book 1997 "Harry Potter"  
      ["J. K. Rowling"]
```

## Constructing and Deconstructing a Value

```
λ> let hp = Book 1997 "Harry Potter"  
      ["J. K. Rowling"]
```

```
λ> let (Book year title authors) = hp
```

## Constructing and Deconstructing a Value

```
λ> let hp = Book 1997 "Harry Potter"  
      ["J. K. Rowling"]
```

```
λ> let (Book year title authors) = hp
```

```
λ> year
```

```
1997
```

```
λ> title
```

```
"Harry Potter"
```

```
λ> authors
```

```
["J. K. Rowling"]
```

# Naming Conventions

Type names start with **capital** letters.

# Naming Conventions

Type names start with **capital** letters.

Function and **variable** names start with **lowercase** letters.

# Naming Conventions

Type names start with **capital** letters.

Function and variable names start with **lowercase** letters.

Type variables start with **lowercase** letters.

# Naming Conventions

Type names start with **capital** letters.

Function and variable names start with **lowercase** letters.

Type variables start with **lowercase** letters.

Often the **same name** is used for the **type** and the **data constructor**.

```
data IntPair = IntPair Int Int
```

# Type Synonyms

```
type Year = Int
```

## Type Synonyms

```
type Year = Int
```

```
type Title = String
```

```
type Author = String
```

```
data BookInfo = BookInfo Year Title [Author]
```

## Type Synonyms

```
type Year = Int
```

```
type Title = String
```

```
type Author = String
```

```
data BookInfo = BookInfo Year Title [Author]
```

Symbolic names are **not enforced**:

```
("J. K. Rowling" :: Author) :: String
```

is a valid expression.

## Data Types vs. Tuples

```
type Cartesian2D = (Double,Double)
```

VS.

```
data Cartesian2D = Cartesian2D Double Double
```

## Data Types vs. Tuples

```
type Cartesian2D = (Double,Double)
```

VS.

```
data Cartesian2D = Cartesian2D Double Double
```

Suppose we want to represent **polar** coordinates.

## Data Types vs. Tuples

```
type Cartesian2D = (Double,Double)
```

VS.

```
data Cartesian2D = Cartesian2D Double Double
```

Suppose we want to represent **polar** coordinates.

```
type Polar2D = (Double,Double) == Cartesian2D
```

On the other hand,

```
type Polar2D = Polar2D Double Double /= Cartesian2D
```

## Data Types vs. Tuples

```
type Cartesian2D = (Double,Double)
```

VS.

```
data Cartesian2D = Cartesian2D Double Double
```

Suppose we want to represent **polar** coordinates.

```
type Polar2D = (Double,Double) == Cartesian2D
```

On the other hand,

```
type Polar2D = Polar2D Double Double /= Cartesian2D
```

**Data types** allow **distinguishing** at **compile time** between **semantically different** types which have the **same syntactical** structure.

# Algebraic Data Types

Algebraic data types have  $\geq 1$  data constructor.

# Algebraic Data Types

Algebraic data types have  $\geq 1$  data constructor.

```
data Bool = True | False
```

# Algebraic Data Types

Algebraic data types have  $\geq 1$  data constructor.

```
data Bool = True | False
```

```
type Mass = Double
```

```
type Volume = Double
```

```
data Cargo = Solid Mass | Liquid Volume  
           | Gas Volume | Plasma Volume
```

# Outline

1. Vague Definitions
2. Algebraic Data Types
3. Parameterised and Recursive Data Types
4. Typeclasses

## Parameterised Data Types

```
data Pair a = Pair a a
```

## Parameterised Data Types

```
data Pair a = Pair a a
```

```
λ> let p1 = Pair True False
```

```
λ> :type p1
```

```
p1 :: Pair Bool
```

## Parameterised Data Types

```
data Pair a = Pair a a
```

```
λ> let p1 = Pair True False
```

```
λ> :type p1
```

```
p1 :: Pair Bool
```

```
λ> let p2 = Pair "Hello" "World"
```

```
λ> :type p2
```

```
p2 :: Pair String
```

# The Maybe Type

```
data Maybe a = Just a | Nothing
```

Very often used to represent a container which may transport a data item or may be empty.

# The List Type

# The List Type

```
data List a = Cons a (List a) | Nil
           deriving (Show)
```

Nil

# The List Type

```
data List a = Cons a (List a) | Nil
           deriving (Show)
```

```
Nil
```

```
Cons 3 Nil
```

# The List Type

```
data List a = Cons a (List a) | Nil
           deriving (Show)
```

```
Nil
```

```
Cons 3 Nil
```

```
Cons 2 (Cons 3 Nil)
```

## The List Type

```
data List a = Cons a (List a) | Nil
           deriving (Show)
```

```
           Nil
         Cons 3 Nil
       Cons 2 (Cons 3 Nil)
     Cons 1 (Cons 2 (Cons 3 Nil))
```

# The BinaryTree Type

## The BinaryTree Type

```
data Tree a = Node a (Tree a) (Tree a)
```

## The BinaryTree Type

```
data Tree a = Node a (Tree a) (Tree a)
            | Empty
            deriving (Show)
```

# Outline

1. Vague Definitions
2. Algebraic Data Types
3. Parameterised and Recursive Data Types
4. Typeclasses

# Typeclasses

A **typeclass** is a **collection** (class) of **types**.

# Typeclasses

A **typeclass** is a **collection** (class) of **types**.

A **typeclass** specifies what **properties** a **type** must have.

# Typeclasses

A **typeclass** is a **collection** (class) of **types**.

A **typeclass** specifies what **properties** a **type** must have.

A **typeclass** specifies which **functions** should be defined for a **type**.

## An Example of a Typeclass

```
class BasicEq foo where
    isEqual :: foo -> foo -> Bool
```

A type `foo` belongs to the typeclass `BasicEq` if there exists a version of the function `isEqual` defined for it.

## An Example of a Typeclass

```
class BasicEq foo where
  isEqual :: foo -> foo -> Bool
```

A type `foo` belongs to the typeclass `BasicEq` if there exists a version of the function `isEqual` defined for it.

One can say that, to verify whether a value of type `a` appears in a list of `a`, we need to be able to compare values of type `a` in the following way:

```
isElement :: BasicEq a => a -> [a] -> Bool
```

## Saying That a Type Belongs to a Typeclass

```
instance BasicEq Bool where
  isEqual True True = True
  isEqual False False = True
  isEqual _ _ = False
```

## Typeclasses `Show` and `Read` (in a nutshell)

```
class Show a where  
    show :: a -> String
```

```
class Read a where  
    read :: String -> a
```

# Automatic Derivation of Instances

Instances of `Show`, `Read`, `Eq`, `Ord`, `Bounded`, `Enum` can be derived automatically.

```
data Maybe a = Just a | Nothing
           deriving (Show, Read, Eq)
```
